STA 303/1002: Class 12- Logistic Regression

Observed — Estimated

- What did we learn about Binary Logistic Regression?
  - Underlying probability distribution of response: Bernoulli
    - Outcome: Response variable, Y-binary $\begin{cases} 0 \\ 1 \end{cases}$

$y = \begin{cases} 0 \\ 1 \end{cases}, \quad \hat{y}$

$\pi = \begin{cases} 0 \\ 1 \end{cases}, \quad 0 < \hat{\pi} < 1$

  - Model:

$$\text{logit}(\pi) \;—\; \log\left(\frac{\pi}{1-\pi}\right) = f(\mathbf{X}; \boldsymbol{\beta})$$

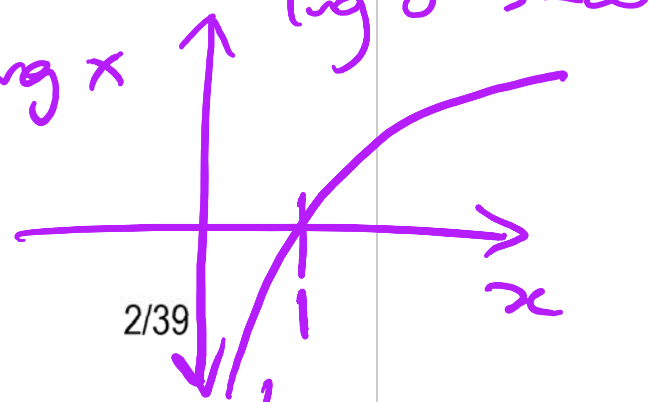
    where $f(\mathbf{X}; \boldsymbol{\beta})$ is a $\boxed{\text{linear function of the } \beta\text{'s}}$
    - Predictor variables, $\mathbf{X}$: categorical and/or continuous

Do not compare π, $\hat{\pi}$

  - Estimation: MLE via Fisher scoring algorithm
  - Interpretation of β's: Hold other X's constant, the odds of Y=1 change by factor of e^{β}.
  - Estimate Odds, Odds ratio, $e^{\beta(a-b)}$
  - Inference:
    - Wald tests and confidence intervals
    - Compare models: LRT: 1) >1 β, 2) 1 β, 3) Global

Fit vs Null

$\log 0 \to -\infty$



$\log 1 = 0$

y_i	i
0	1
1	2
0	⋮
0	
1	
0	N

$$\pi = P(\text{"success"}) = \frac{y_i}{m_i = 1}$$

Binomial Logistic Regression

- What did we learn about Binomial Logistic Regression?
  - Underlying probability distribution of response: Binomial
    - Outcome: Response variable, Y-count variable
  - Model:

$$\log\left(\frac{\pi}{1-\pi}\right) = f(\mathbf{X};\boldsymbol{\beta})$$

$\pi_i = \frac{y_i}{m_i}$

where $f(\mathbf{X};\boldsymbol{\beta})$ is a linear function of the β's

$\hat{\pi}_i$

  - Estimate Odds, Odds Ratio and π
  - Inference: Wald or LRT
  - We can do more tests for model adequacy than in Binary logistic regression.
- Deviance GOF test: Fitted vs Saturated
- Quote of the week: "All models are wrong but some are useful."- *Unknown*.

Which is an example of a Generalized Linear Model?

$E(y|x)$

(a) $\mu[Y|X_1, X_2] = \beta_0 + \beta_1 X_1 + \beta_2 X_2$

(b) $\mu[Y|X_1] = \beta_0 + \beta_1 X_1 + \beta_2 X_1^2$ (X_1, X_2)

(c) $\mu[Y|X_1, X_2] = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3$

(d) $\mu[Y|X_1, X_2] = \beta_0 + \beta_1 X_1 + \beta_2 \log(X_2)$

(e) $\mu[Y|X_1] = \beta_0 + \beta_1 10^{X_1}$

(f) $\mu[Y|X_1, X_2] = \dfrac{\beta_0 + \beta_1 X_1}{\beta_0 + \beta_2 X_2}$

(g) $\mu[Y|X_1] = \beta_0 + \exp(\beta_1 X_1)$

(h) $\mu[Y|X_1] = \beta_0 \exp(\beta_1 X_1)$ — H.W

(i) $\mu[Y|X_1, X_2] = \beta_1 X_1 \exp(\beta_0 + \beta_2 X_2)$

$\underline{g}(E(y|x)) \sim \underline{\text{linear}}$ ito β's

$E(y|x) \sim$ linear ito β's.

$\Rightarrow$ General Linear Reg.

$\underline{g(\mu) = \mu}$.

$g(\mu) \neq \mu$ < $g(\mu) = \log(\mu)$, $g(\mu) = \text{logit}(\mu)$

(g) $\log \mu = \log(\beta_0 + e^{\beta_1 X_1})$.

(h) $\log \mu = (\log \beta_0) + \beta_1 X_1$

(i) $\log \mu = \log(\beta_1 X_1) + \beta_0 + \beta_2 X_2$.

$= (\beta_0 + \log \beta_1 + \log X_1) + \beta_2 X_2$

Which is false?

(i) A Logistic regression model is a Generalized Linear Model. TRUE

(ii) Logistic regression assumes that there is a linear relationship between logits and explanatory variables. $\text{logit}(\pi) = X\beta$.

$\boxed{\text{(iii)}}$ Logistic regression describes population proportion or probability as a linear function of explanatory variables. should be of β's.

(iv) Logistic regression is a nonlinear regression model. TRUE.

Model Assumptions for Binomial Logistic Regression

$$E\left(\frac{y_i}{m_i}\right) = \pi_i$$

$$Var\left(\frac{y_i}{m_i}\right) = \frac{\pi_i(1-\pi_i)}{m_i}$$

1. Underlying probability model for response is Binomial.
   - Variance is not constant; is a function of the mean.
2. Observations are independent. (based on design of study)
3. The form of the model is correct
   - Linear relationship between logits and explanatory variables
   - All relevant variables are included; irrelevant ones excluded
4. Sample size is large enough for valid inference-tests and CIs. (Recall large-sample properties of MLEs.)
   - Check for outliers.

$$E(\varepsilon_i) = 0$$

$$Var(\varepsilon_i) = \sigma^2$$

What is the SATURATED Model?

y_i

- Observed response proportion:

$0 \le y_i \le m_i$

$0 \le \pi_i \le 1$

$$\bar{\pi}_i = \frac{y_i}{m_i}$$

- Observed or Empirical logits: (S- "saturated")

$$\log\left(\frac{\bar{\pi}_{S,i}}{1-\bar{\pi}_{S,i}}\right) = \log\left(\frac{y_i}{m_i - y_i}\right) = \log\left(\frac{y_i/m_i}{1-y_i/m_i}\right)$$

- Fits the model exactly with the data
- Most general model possible for the data.

Which Models are often compared?

Consider one explanatory variable, X with n unique levels for the outcome, $Y \sim (Bin(m, \pi))$

- Saturated (FULL) Model: as many parameter coefficients as n

$$logit(\widehat{\pi}) = \boxed{\widehat{\alpha}_0 + \widehat{\alpha}_1 \mathbb{1}_1 + \cdots + \widehat{\alpha}_{n-1} \mathbb{1}_{n-1}}$$

$n-1+1=n$.

- Fitted (REDUCED) Model: nested within a FULL model; has $(p+1)$ parameters

$p+1$, $p<n$.

$$logit(\widehat{\pi}) = \widehat{\beta}_0 + \widehat{\beta}_1 X$$

- NULL Model: Intercept only model

$$logit(\widehat{\pi}) = \widehat{\gamma}_0$$

Checking model adequacy: Form of the model

Deviance Goodness -Of -Fit (G-O-F) Test

- To check model adequacy in binomial logistic regression, we can use the Deviance Goodness -Of -Fit (G-O-F) Test.
- Analogous to GOF test for comparing 2 models in Linear Regression.

SATURATED.

- Form of hypotheses: H_0: REDUCED model, H_a: FULL model
- The DEVIANCE GOF test compares the fitted model (M) to the saturated model (S).

$$H_0 : (Fitted) logit(\widehat{\pi}) = \widehat{\beta}_0 + \widehat{\beta}_1 X$$

$$H_a : (Saturated) logit(\widehat{\pi}) = \widehat{\alpha}_0 + \widehat{\alpha}_1 \mathbb{1}_1 + \cdots + \widehat{\alpha}_{n-1} \mathbb{1}_{n-1}$$

Compared to Saturated model: Deviance G-O-F test

- Uses LRT
- Sometimes called "Drop-in-Deviance" test
- as extra-sum-of-squares tests; based on the deviance residual
- Hypotheses:

  H_0: $logit(\pi) = \alpha_0 + \alpha_1 X$

  (Fitted model fits data as well as Saturated model)

  H_a: $logit(\pi) = \beta_0 + \beta_1 \mathbb{1}_1 + \cdots + \beta_{n-1} \mathbb{1}_{n-1}$

  (Saturated model is better)
- Test Statistic:

$$Deviance = -2 \log \left(\frac{\mathcal{L}_R}{\mathcal{L}_F} \right) = -2 \log \left(\frac{\mathcal{L}_M}{\mathcal{L}_S} \right)$$

- Under H_0, *Deviance* $\sim$ Chi-square distribution with $n - (p+1)$ df.
- Warning: This is an asymptotic approximation, so it works better if each $m_i > 5$.)

Calculating the Deviance test statistic

y_1
y_2
$\vdots$
y_n

Recall underlying model of Y: $Y_i \sim Binomial(m_i, \pi_i)$

$$P(Y_i = y_i) = \underbrace{\binom{m_i}{y_i} \pi_i^{y_i} (1 - \pi_i)^{m_i - y_i}}, \quad y_i = 0, 1, \ldots, m_i$$

$i = 0, 1, 2, \ldots, n$

Hence the likelihood is:

$$\mathcal{L} = \Pi_{i=1}^{n} \binom{m_i}{y_i} \pi_i^{y_i} (1 - \pi_i)^{m_i - y_i}$$

where

$$\pi_i = \frac{\exp(\beta_0 + \beta_1 X_{i1} + \ldots + \beta_p X_{ip})}{1 + \exp(\beta_0 + \beta_1 X_{i1} + \ldots + \beta_p X_{ip})}$$

Calculating the Deviance test statistic

constant

Then the log-likelihood is:

$$\log \mathcal{L} = \sum_{i=1}^{n} [y_i \log(\pi_i) + (m_i - y_i)\log(1 - \pi_i) + \underline{\log \binom{m_i}{y_i}}]$$

The deviance test statistic is based on a ratio of likelihoods.

$$
\begin{aligned}
Deviance &= -2 \log \frac{\mathcal{L}_M}{\mathcal{L}_S} \\
&= -2(\log \mathcal{L}_M - \log \mathcal{L}_S) \\
&= 2(\log \mathcal{L}_S - \log \mathcal{L}_M)
\end{aligned}
$$

log L_S

- Q: A Saturated Model has *Deviance* = 0

$L_S = 1$

Calculating the Deviance test statistic

y_i $\quad$ $\hat{y}_i$

$$
\begin{aligned}
Deviance &= 2(\log \mathcal{L}_S - \log \mathcal{L}_M) \\
&= 2\sum_{i=1}^{n} \left[y_i \log\left(\frac{y_i}{m_i}\right) + (m_i - y_i)\log\left(\frac{m_i - y_i}{m_i}\right) + \log\binom{m_i}{y_i} \right. \\
&\qquad \left. - y_i \log\left(\frac{\widehat{y}_i}{m_i}\right) - (m_i - y_i)\log\left(\frac{m_i - \widehat{y}_i}{m_i}\right) - \log\binom{m_i}{y_i} \right] \\
&= 2\sum_{i=1}^{n} \left[y_i \log(y_i) + (m_i - y_i)\log(m_i - y_i) \right. \\
&\qquad \left. - y_i \log(\widehat{y}_i) - (m_i - y_i)\log(m_i - \widehat{y}_i) \right] \\
&= 2\sum_{i=1}^{n} \left[y_i \log\left(\frac{y_i}{\widehat{y}_i}\right) + (m_i - y_i)\log\left(\frac{m_i - y_i}{m_i - \widehat{y}_i}\right) \right]
\end{aligned}
$$

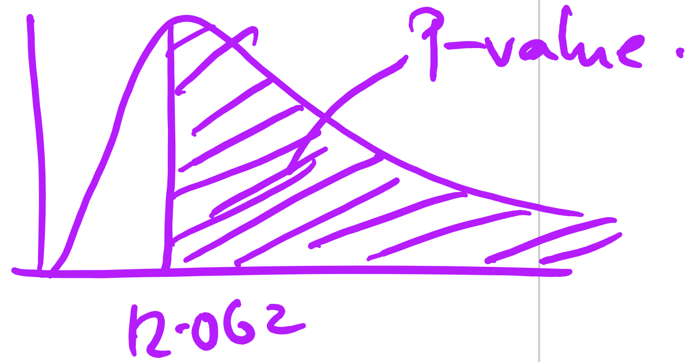
Case Study IV Exercise: Using Deviance

Using R output,

Q: Determine whether a saturated model is an improvement over the simpler model with linear function of log(*Area*).

(In R, we get deviance of a model by using `deviance('fittedmodel')`)

- Hypotheses: H_0: Fitted $\Rightarrow$ $\text{logit}(\pi) = X\beta$.
  H_a: Saturated $\text{logit}(\pi) = $ (based exactly on data).
- Test Statistic: Deviance=12.062
  In R: Residual deviance
- Distribution of TS: $\sim \chi^2_{16}$
- P-value: $P(\chi^2_{16} \geq 12.062) = 0.74$



- Conclusion: The data are consistent with H_0; the simpler model with linear function of log(*Area*) is adequate (fits as well as the saturated model).

Binomial Logistic Regression: Interpreting Deviance

- Smaller deviance leads to larger p-value and vice versa.
- Large p-values means:
  - Fitted model is adequate, OR
  - Test is not powerful enough to detect inadequacies
- Small p-values means:
  - Fitted model is not adequate; consider a more complex model with more explanatory variables or higher order terms and so on, OR
  - Response distribution is not adequately modelled by the Binomial distribution, OR → Eg, Poisson.
  - There are severe outliers.

Can we do a Deviance GOF test in Binary case?

In Binary logistic regression case, $\boxed{m_i = 1}$ for all i, and $y_i = \begin{cases} 0 \\ 1 \end{cases}$

Then deviance becomes:

$$\begin{aligned} \textit{Deviance} &= 2 \sum_{i=1}^{n} \big[y_i \log(y_i) + (1 - y_i) \log(1 - y_i) \\ &\qquad - y_i \log(\widehat{y}_i) - (1 - y_i) \log(1 - \widehat{y}_i) \big] \\ &= 2 \sum_{i=1}^{n} \big[- y_i \log(\widehat{y}_i) - (1 - y_i) \log(1 - \widehat{y}_i) \big]. \end{aligned}$$

Sat, S

Fitted, M.

Notice that the terms that came from the saturated model, $\log \mathcal{L}_S$ are gone, so deviance is no longer useful to compare $\mathcal{L}_M$ with $\mathcal{L}_S$.

Model assessment in Binomial Logistic Regression

- Is linear relationship appropriate?
  - Plot observed logit versus quantitative explanatory variable
- Is the form of the model correct?
  - Use Wald or LRT tests
- Is saturated model better than fitted model?
  - Deviance GOF test
- Are there outliers?
  - Examine standardized residuals: Pearson and Deviance Residuals
- Consider other model fit statistics: AIC, BIC
- Other issues/concerns in model fitting

Residuals: Pearson and Deviance

- Response (raw) residuals: (*observed* − *fitted*) proportion

$$\widehat{\pi}_{S,i} - \widehat{\pi}_{M,i} = \frac{y_i}{m_i} - \widehat{\pi}_{M,i}$$

- Standardized residuals:
  (1) Pearson Residuals: uses estimate of s.d. of Y (in denominator)

$$P_{res,i} = \frac{y_i - m_i\widehat{\pi}_{M,i}}{\sqrt{m_i\widehat{\pi}_{M,i}(1 - \widehat{\pi}_{M,i})}}$$

  (2) Deviance Residuals: defined so that the sum of the squares of the residuals is the deviance

$$\begin{aligned} D_{res,i} = & \operatorname{sign}(y_i - m_i\widehat{\pi}_{M,i}) \\ & \times \sqrt{2\left\{y_i \log\left(\frac{y_i}{m_i\widehat{\pi}_{M,i}}\right) + (m_i - y_i)\log\left(\frac{m_i - y_i}{m_i - m_i\widehat{\pi}_{M,i}}\right)\right\}} \end{aligned}$$

Response, Pearson and Deviance Residuals in R

- Response residuals

```
residuals(fitbl, type="response")
```

- Pearson residuals

```
residuals(fitbl, type="pearson")
```

- Deviance residuals

```
residuals(fitbl, type="deviance")
```

Case Study IV Example: Were there outliers in the data?

	Pearson, $P_{res,i}$	Deviance, $D_{res,i}$
Asymptotic Dist.	$N(0,1)$	$N(0,1)$
R code	`pearson`	`deviance`
Possible outlier if	$\lvert P_{res,i} \rvert > 2$	$\lvert D_{res,i} \rvert > 2$
Outlier if	$\lvert P_{res,i} \rvert > 3$	$\lvert D_{res,i} \rvert > 3$
Under small n	D_{res} closer to $N(0,1)$ than P_{res}	
$\hat{\pi}$ close to 0 or 1	P_{res} are unstable; related to instability of Wald	

- Results: Both are $< \lvert 2 \rvert$, so no outliers

Other Model Fit Statistics

- Useful for comparing models with same response and same data
- Two popular fit statistics: AIC and BIC; combines log-likelihood with a penalty
  1. Akaike's Information Criterion (AIC)

  $$AIC = -2 \log \mathcal{L} + 2(p + 1)$$

  2. Schwarz's (Bayesian Information) Criterion (BIC)

  $$BIC = -2 \log \mathcal{L} + (p + 1) \log N$$

  where
    - p-number of explanatory variables, and
    - $N = \sum_{i=1}^{n} m_i$.
- Example: see AIC, BIC for Case IV model

Problems and Complications common to Linear and Logistic Regression

- *Extrapolation*- don't make inferences/predictions outside range of observed data; model may no longer be appropriate.
- *Multicollinearity*- highly correlated explanatory variables; difficult to assess individual effects on response. Consequences include:
  - Unstable fitted equation
  - Coefficient that should be statistically significant is not
  - Coefficient may have the wrong sign
  - Sometimes, large s.e. of $\widehat{\beta}$
  - Sometimes numerical procedure to find MLEs does not converge

Problems and Complications common to Linear and Logistic Regression

- *Extrapolation*- don't make inferences/predictions outside range of observed data; model may no longer be appropriate.
- *Multicollinearity*- highly correlated explanatory variables; difficult to assess individual effects on response. Consequences include:
  - Unstable fitted equation
  - Coefficient that should be statistically significant is not
  - Coefficient may have the wrong sign
  - Sometimes, large s.e. of $\widehat{\beta}$
  - Sometimes numerical procedure to find MLEs does not converge

Problems and Complications common to Linear and Logistic Regression

- *Influential points*- an observation is influential if its removal substantially changes estimated coefficients (such as, fitted $\widehat{\beta}$'s, deviance)
- *Model Building*- choosing explanatory variables and their forms (eg. polynomial terms, interaction and transformations) tend to overfit the data; should build model on training data and test on test data (cross validation).

Problems and Complications common to Linear and Logistic Regression

- *Influential points*- an observation is influential if its removal substantially changes estimated coefficients (such as, fitted $\widehat{\beta}$'s, deviance)
- *Model Building*- choosing explanatory variables and their forms (eg. polynomial terms, interaction and transformations) tend to overfit the data; should build model on training data and test on test data (cross validation).

Two problems specific to Logistic Regression

1. **Extra-binomial variation**
   - variance of Y_i greater than $m_i \pi_i (1 - \pi_i)$
   - also called "over dispersion"
   - does not bias $\widehat{\beta}$'s but s.e. of $\widehat{\beta}$'s will be too small (too small p-values, too narrow CIs)

SOLUTION: add one more parameter to the model, ψ- dispersion parameter. Then $\text{Var}(Y_i) = \psi m_i \pi_i (1 - \pi_i)$.

Two problems specific to logistic regression

2. Complete and Quasi-complete separation

- *Complete separation*:
  - one or a linear combination of explanatory variables perfectly predict whether $Y = 1$ or $Y = 0$
  - In Binary response, when $y_i = 1$, $\hat{y}_i = 1$, then $\sum_{i=1}^{n}\{y_i \log(\hat{y}_i) + (1 - y_i)\log(1 - \hat{y}_i)\} = 0$.
  - MLE's cannot be computed
- *Quasi-complete separation*:
  - explanatory variables predict $Y = 1$ or $Y = 0$ almost perfectly (just a few points wrong)
  - MLE's are numerically unstable

SOLUTION: simplify the model. Other options- penalized maximum likelihood, exact logistic regression, bayesian methods

Using Logistic Regression for Classification

- Want: predict outcome as

$$y^*|(x_1^*, x_2^*, \ldots, x_p^*) = \begin{cases} 1 \\ 0 \end{cases}$$

- Do: calculate $\widehat{\pi}_M^*$- the estimated probability that $y^* = 1$ based on the fitted model given $X_1 = x_1^*, X_2 = x_2^*, \ldots, X_p = x_p^*$. From this we want to predict that

$$y^* = \begin{cases} 1 & \text{if } \widehat{\pi}_M^* \text{ is large} \\ 0 & \text{if } \widehat{\pi}_M^* \text{ is small} \end{cases}$$

- Need: choose a cut-off probability to distinguish between large and small.

Classification: Approaches to choosing a threshold

Approach 1 - Set cut-off probability as 0.5

- If $\widehat{\pi}_M^* > 0.5$, classify y^* as 1
- Useful if there are equal numbers of 1's and 0's
- Useful if false negatives and false positives are equally bad.

Classification: Approaches to choosing a threshold

Approach 2- Find “best” cut-off probability from data.

- Try different cut-offs and see which gives fewest incorrect classifications
- Useful if proportions of 1’s and 0’s in data reflect their relative proportions in the population
- Likely to overestimate the proportions of correct predictions that model makes. Then, one should assess model correct classification rates on different data than was used to fit the model.
